(57) **ABSTRACT**

To provide a specimen storage device capable of preventing liquid such as immersion oil and the like attached to the specimen plate from leaking to the outside of the rack and capable of enhancing the operation efficiency by automating the supply and discharge of the rack. Provided is a specimen storage device which stores a imaged specimen plate in a bottomed-shaped rack having an opening at an upper part, the specimen storage device including a rack transport mechanism which transports the rack with the opening directed upward, and a specimen transport mechanism which transports the specimen in an up-down direction, wherein the rack transport mechanism transports the rack to a predetermined specimen storage position, and the specimen transport mechanism stores the specimen to the rack positioned at the specimen storage position from above the rack.

SPECIMEN STORAGE DEVICE, SPECIMEN STORING METHOD, AND RACK

RELATED APPLICATIONS

This application claims priority under 35 U.S.C. §119 to Japanese Patent Application No. 2012-215853 filed on Sep. 28, 2012, the entire content of which is hereby incorporated by reference.

FIELD OF THE INVENTION

The present invention relates to a specimen storage device and a specimen storing method for storing a specimen performed with imaging by a specimen imaging apparatus, and the like in a rack, and a rack.

BACKGROUND OF THE INVENTION

An imaging apparatus for imaging a specimen, which is created by smearing a sample such as blood on a slide glass and performing staining processing, and the like, with a microscope and a camera is conventionally known. An image imaged by the imaging apparatus is used for automatic cell classification, and manual cell classification by an operator.

In this type of specimen imaging apparatus, the supplied specimen is automatically transported to the microscope, and automatically collected to a predetermined collecting location after being performed with imaging by the camera. For example, in the specimen imaging apparatus disclosed in U.S. Patent Application Publication No. 2011/304722, after a magazine storing a specimen is installed in a cavity, a handling device grips the specimen and takes out the specimen from the magazine, and then transports the specimen to an optical system including the microscope, and the like. The specimen after the image is imaged in the optical system is again returned to the magazine by the handling device.

U.S. Pat. No. 4,501,495 discloses an automated microscope system for slidably dropping a tray supporting a plurality of slide glasses into a storage box at a predetermined discharging stage after imaging is finished to store the slide glasses in a standing manner in the storage box.

The magazine used in the specimen imaging apparatus described in U.S. Patent Application Publication No. 2011/304722 stores the plurality of specimens so as to be lined in the up-down direction in a horizontal posture. An opening is formed at a side surface of the magazine, so that the specimen is placed in and taken out through the opening.

However, if immersion oil is used in the imaging of the specimen, the immersion oil that attached to the specimen drops in various directions thus attaching to the side surface, the bottom surface, and the like inside the magazine, and may also attach to other specimens in the magazine. In particular, if the immersion oil attached to the magazine leaks to the outside from the opening of the side surface, the periphery of the magazine may get dirty. Thus, a step for washing the periphery of the magazine may become necessary, or an immersion oil may possibly attach to a mechanism, or the like at the periphery of the magazine thus adversely affecting of the operation of such mechanism, and the like. Furthermore, since the magazine itself does not move inside the specimen imaging apparatus, the transportation distance of the specimen until reaching the magazine may become long, which increases the possibility of oil dropping during the transportation and getting the transportation path dirty.

The storage box used in the automated microscope system described in U.S. Pat. No. 4,501,495 is bottomed and has the

2

upper side opened, where a plurality of slide glasses is stored therein in a standing state. However, since the storage box itself is fixed and does not move, the transportation path of the slide glass becomes long, which increases the possibility of the immersion oil dropping during the transportation and getting the transportation path dirty. One storage box is merely set in the specimen imaging apparatus, and thus the relevant storage needs to be changed to another storage box by humans when it becomes filled with slide glasses. The apparatus is thus inevitably stopped during such time thus degrading the operation efficiency.

SUMMARY OF THE INVENTION

The scope of the present invention is defined solely by the appended claims, and is not affected to any degree by the statements within this summary.

A first aspect of the present invention is a specimen storage device for storing an imaged specimen plate in a rack which is bottomed-shaped and has an opening at an upper part, the specimen storage device comprising:

a rack transport mechanism configured to transport the rack with the opening directed upward; and

a specimen transport mechanism configured to transport the specimen plate in an up-down direction, wherein

the rack transport mechanism transports the rack to a predetermined specimen storage position, and the specimen transport mechanism stores the specimen plate in the rack positioned at the specimen storage position from above the rack.

A second aspect of the present invention is a specimen storing method used in a specimen storage device for storing an imaged specimen plate in a rack which is bottomed-shaped and has an opening at an upper part, the method comprising the steps of:

automatically transporting the rack to a predetermined specimen storage position with the opening directed upward; and

automatically storing the specimen plate to the rack positioned at the specimen storage position from above the rack by transporting the specimen plate in an up-down direction.

A third aspect of the present invention is a rack used in a specimen storage device for storing an imaged specimen plate, wherein

the rack is formed to be a bottomed-shape having an opening at an upper part and includes a supporting section to support the specimen plate in a standing state.

A fourth aspect of the present invention is a specimen storage device comprising:

a rack formed to a bottomed-shape having an opening at an upper part and storing an imaged specimen plate;

a rack transport mechanism configured to transport the rack with the opening directed upward; and

a specimen transport mechanism configured to transport the specimen plate in an up-down direction; wherein

the rack transport mechanism transports the rack to a predetermined specimen storage position, and the specimen transport mechanism stores the specimen plate in the rack positioned at the specimen storage position from above the rack.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an overall configuration diagram showing a specimen testing system according to an embodiment of the present invention;

3

FIG. 2 is a perspective view of a specimen plate and a cassette;

FIGS. 3A to 3C are front explanatory views showing operation of a cassette transport mechanism (lateral transport section) in a specimen transporter;

FIG. 4 is a schematic side view showing a vertical transport mechanism in the specimen transporter;

FIGS. 5A and 5B are schematic bottom views describing an opening/closing operation of a gripping nail;

FIG. 6 is a plan explanatory view showing a horizontal transport mechanism;

FIG. 7 is a cross-sectional view taken along line VII-VII of FIG. 6;

FIGS. 8A and 8B are cross-sectional views taken along line VIII-VIII of FIG. 6;

FIGS. 9A to 9C are plan explanatory views showing an operation of the horizontal transport mechanism;

FIGS. 10A and 10B are plan explanatory views showing the operation of the horizontal transport mechanism;

FIG. 11 is a side view of a rack;

FIG. 12 is a plan view of the rack;

FIG. 13 is a front view showing a lower part of the rack;

FIG. 14 is a cross-sectional view taken along line XIV-XIV of FIG. 12;

FIG. 15 is a cross-sectional explanatory view of a rack transport mechanism seen from the side;

FIG. 16 is a cross-sectional explanatory view of the rack transport mechanism seen from the front;

FIG. 17 is a cross-sectional explanatory view of the rack transport mechanism seen from the front;

FIGS. 18A to 18C are schematic plan views describing the operation of the lateral transport section of the rack transport mechanism;

FIGS. 19A to 19C are schematic plan views describing the operation of the lateral transport section of the rack transport mechanism;

FIGS. 20A and 20B are schematic plan views describing the operation of the lateral transport section of the rack transport mechanism;

FIG. 21 is a side explanatory view showing a longitudinal transport section (retreated state) of the rack transport mechanism;

FIG. 22 is a side explanatory view showing the longitudinal transport section (advanced state) of the rack transport mechanism; and

FIGS. 23A to 23C are schematic side views describing the operation of the longitudinal transport section.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The preferred embodiments of the present invention will be described hereinafter with reference to the drawings.

An embodiment of a specimen testing system (specimen imaging system) of the present invention will be hereinafter described with reference to the drawings.

[Schematic Configuration of Specimen Testing System]

FIG. 1 is an overall configuration diagram showing a specimen testing system according to one embodiment of the present invention.

A specimen testing system 1 of the present embodiment is a system that is configured by a specimen creating apparatus 2, a specimen transporter 3, and a specimen imaging apparatus (specimen testing apparatus) 4, and that automatically performs a series of operations from creating the specimen of the sample such as blood up to imaging (testing, analyzing) of the specimen.

4

In the present specification, description will be made assuming the X direction shown in FIG. 1 as left-right direction, Y direction as front-back direction, and Z direction as up-down direction. In FIG. 1, the lower side is assumed as the front side and the upper side is assumed as the back side, the specimen creating apparatus 2 is arranged at a right side portion of the specimen testing system 1, the specimen imaging apparatus 4 is arranged at a left side portion, and the specimen transporter 3 is arranged between the left and the right of the specimen creating apparatus 2 and the specimen imaging apparatus 4. The specimen transporter 3 has one part arranged to overlap the front side of the specimen imaging apparatus 4. Furthermore, in the present specification, "lateral" is sometimes described to mean the left-right direction, and "longitudinal" is sometimes described to mean the front-back direction.

The specimen creating apparatus 2 smears blood, which is the sample, on a slide glass, and performs processing such as drying, staining, and the like to create a specimen plate (hereinafter also simply referred to as "specimen") 10. FIG. 2 is a perspective view of the specimen plate 10 and a cassette 11. The specimen plate 10 is made from a rectangular-shaped plate material such as glass, and the sample is smeared at a central portion 10a. Sample information (barcode indicating sample number, date, receipt number, name, information of sample, etc.) 10b is printed at an upper part of the specimen plate 10.

The created specimen plate 10 is supplied to the next specimen transporter 3 while being stored in the cassette 11. A cassette supplying section 2a for supplying the cassette 11 having the specimen plate 10 therein to the specimen transporter 3 is provided at a back part on the left side of the specimen creating apparatus 2. The operation of each mechanism section in the specimen creating apparatus 2 is controlled by a control section 2b. The control section 2b includes a CPU, a storage unit, and the like, and is communicably connected with other devices by way of a communication section 2c.

The cassette 11 storing the specimen plate 10 therein is a flat case formed to a substantially T-shape in front view. At a middle of an upper end portion of the cassette 11 is formed an insertion port 11a for inserting the specimen plate 10. The specimen plate 10 inserted to the insertion port 11a projects out from the cassette 11 so that the sample information 10b at the upper part is exposed to the outside. A collar section 11b is formed at the upper part of the cassette 11 so as to project out to both left and right sides.

The specimen transporter 3 has a function of transporting the specimen plate 10 (cassette 11) received from the specimen creating apparatus 2 to the adjacent specimen imaging apparatus 4. Specifically, the specimen transporter 3 takes out the specimen plate 10 from the cassette 11 and transports the specimen plate 10 to the specimen imaging apparatus 4 through a predetermined path. The specimen transporter 3 also has a function of collecting the specimen plate 10 performed with imaging in the specimen imaging apparatus 4, and storing the specimen plate in a predetermined rack (collecting box) 12 (a function as a specimen storage device). The operation of each mechanism section (specimen storage device 20, specimen transport mechanisms 21 to 23, etc. described later) in the specimen transporter 3 is controlled by a control section 3b. The control section 3b includes a CPU, a storage unit, and the like and is connected to the control section 2b of the specimen creating apparatus 2 by way of communication sections 3c, 2c, so that information can be transmitted and received to perform mutually cooperating

operations. The detailed description of the specimen transporter 3 will be described later.

The specimen imaging apparatus 4 transports the specimen plate 10 received from the specimen transporter 3 to an imaging section 4a to image the sample in the imaging section 4a. The imaged image data is transmitted to a control section 4b. The control section 4b includes a CPU, a storage unit, and the like, and executes predetermined processing such as characteristic extraction processing, identification and classification processing, and the like of the cells based on the image data. The imaged image data and the analysis results may be displayed on a display monitor 4d or output through a printer or the like (not shown). The control section 4b is connected to the control section 3b of the specimen transporter 3 by way of communication sections 4c, 3c, so that information can be transmitted and received to perform mutually cooperating operations. The portion performing the processing related to analysis in the control section 4b of the specimen imaging apparatus 4 may be configured by a single control device such as a personal computer, and the like.

[Configuration of Specimen Transporter 3]

The specimen transporter 3 will be described in detail below.

As shown in FIG. 1, the specimen transporter 3 according to the present embodiment is roughly divided to specimen transport mechanisms 21 to 23, and the specimen storage device 20. The specimen transport mechanisms include a cassette transport mechanism 21, a vertical transport mechanism 22, and a horizontal transport mechanism 23.

The specimen storage device 20 is configured by a rack transport mechanism 24 and a rack accumulating section 75.

The specimen plate 10 is transported to the specimen imaging apparatus 4 by the specimen transport mechanisms 21 to 23, and delivered to the specimen imaging apparatus 4. The specimen plate 10 performed with imaging in the specimen imaging apparatus 4 is stored in a predetermined rack 12 by the horizontal transport mechanism 23, the vertical transport mechanism 22, and the rack transport mechanism 24, and the entire rack 12 can be collected thereafter from the specimen transporter 3.

[Configuration of Cassette Transport Mechanism 21]

The cassette transport mechanism 21 includes a specimen receiving section 26 for receiving and accumulating the cassette 11 having the specimen plate 10 therein supplied from the cassette supplying section 2a of the specimen creating apparatus 2, a cassette collecting section 27 for collecting the cassette 11, from which the specimen plate 10 is taken out, and a lateral transport section 28 for transporting the cassette 11 in the left-right direction.

The specimen receiving section 26 can store a large number of cassettes 11 having the specimen plate 10 therein so as to be lined in the front-back direction. The specimen receiving section 26 can contain, for example, 90 cassettes 11. The specimen receiving section 26 includes a pair of left and right belt conveyors (longitudinal moving section) 26a extending in the front-back direction. The cassette 11 is held by placing the collar section 11b (see FIG. 2) on the left and right belt conveyors 26a, and is moved forward by sending the belt conveyor 26a. Since the specimen receiving section 26 can contain a plurality of specimen plates 10, the difference in the cycle of creating the specimen plate 10 in the specimen creating apparatus 2 (e.g., 120/hour) and the cycle of imaging in the specimen imaging apparatus 4 (e.g., 30/hour) can be absorbed.

The cassette collecting section 27 is arranged adjacent on the left side of the specimen receiving section 26, and can store a large number of cassettes 11, from which the specimen

plate 10 is removed, so as to be lined in the front-back direction. 90 cassettes 11, which is the same number as the specimen receiving section 26, for example, can be stored in the cassette collecting section 27. The cassette collecting section 27 includes a pair of left and right belt conveyors (longitudinal transport section) 27a extending in the front-back direction. The cassette 11 is held by placing the collar section 11b (see FIG. 2) on the left and right belt conveyors 27a, and is moved backward by sending the belt conveyor 27a.

The lateral transport section 28 is arranged at the front end portion of the specimen receiving section 26 and the cassette collecting section 27. The lateral transport section 28 holds the cassette 11 at the front end of the specimen receiving section 26 and transports the same in the left-right direction. In the process of being transported in the left-right direction, the specimen plate 10 is taken out from the cassette 11, and the emptied cassette 11 is collected by the cassette collecting section 27.

Specifically, as shown in FIGS. 3A to 3C, the lateral moving section 28 takes out and holds the cassette 11 at the front end of the specimen receiving section 26, and transports the same in the left direction (arrow x1) (see FIG. 3A). The cassette 11 is positioned at a predetermined specimen transfer position W set at the left side of the front end portion of the cassette transport mechanism 21. At such specimen transfer position W, a gripping section 31 of the vertical transport mechanism 22, to be described later, is waiting on the upper side (upper position H). The gripping section 31 moves to a middle position M on the lower side (arrow z1) to grip the specimen plate 10, and thereafter, returns to the upper side (arrow z2) to remove the specimen plate 10 from the cassette 11 (see FIGS. 3B, C).

The lateral transport section 28 also transports the cassette 11, from which the specimen plate 10 is removed, in the right direction (arrow x2), positions the same at the front end portion of the cassette collecting section 27, and transfers the cassette 11 to the front end portion of the cassette collecting section 27. The cassette collecting section 27 moves the transferred emptied cassette 11 toward the back side with the belt conveyor, and waits until the next reception. The lateral transport section 28 again receives the next cassette 11 from the specimen receiving section 26, and repeatedly performs the operations described above.

The cassette transport mechanism 21 of the present embodiment transports the cassette 11 in a standing posture in all of the specimen receiving section 26, the lateral transport section 28, and the cassette collecting section 27. A complex mechanism for changing the posture of the cassette 11 is thus not necessary, and the structure can be simplified.

As a mode of holding the cassette 11 with the lateral transport section 28, various modes such as a mode of supporting the lower surface or the collar section 11b of the cassette 11 from below, a mode of sandwiching the cassette 11 with a clamp member, and the like, a mode of suctioning with a suction disc, and the like may be adopted. A winding transportation mechanism such as the belt conveyor, chain, and the like, and an expansion/contraction operation mechanism such as a fluid pressure cylinder and the like, can be adopted to transport the held cassette 11 in the left-right direction.

[Configuration of Vertical Transport Mechanism 22]

FIG. 4 is a schematic side view showing the vertical transport mechanism 22 in the specimen transporter 3.

The vertical transport mechanism 22 includes the gripping section (holder) 31 for gripping the specimen plate 10, and the up-down moving section 32 for raising and lowering the gripping section 31 up and down. The gripping section 31 includes a pair of front and back gripping nails 33, and an

7

open/close mechanism **34** for opening/closing the gripping nails **33** forward and backward. The gripping (holding) and the releasing of the specimen plate **10** can be carried out by opening/closing the gripping nails **33** forward and backward. The gripping section **31** is supported to be movable in the up-down direction by a supporting frame **35** of the vertical transport mechanism **22**. The supporting frame **35** includes a guide rail **36** that extends in the up-down direction and that guides the up-down movement of the gripping section **31**.

FIGS. **5A** and **5B** are schematic bottom views describing the opening/closing operation of the gripping nails **33**, FIG. **5A** shows a state in which the gripping nails **33** are closed and FIG. **5B** shows a state in which the gripping nails **33** are opened. One gripping nail **33** includes two projections **33a** arranged side by side on the left and the right. The other gripping nail **33** includes one projection **33b** at a position corresponding to between the two projections **33a**. The gripping nails **33** thus sandwich and grip the specimen plate **10** at three points with the three projections **33a**, **33b**. The projections **33a**, **33b** are made from an elastic material such as rubber. The projection **33a** of one gripping nail **33** is formed to a cone shape, and the projection of the other gripping nail **33** is formed to a cuboid shape or a cubic shape. The contacting surface with respect to the specimen plate **10** can be reduced by forming the projection **33a** to a cone shape, thus enhancing the gripping pressure.

The open/close mechanism **34** includes a drive motor **37**, an operation rod **38** coupled to an output shaft **37a** of the drive motor **37**, a pair of operation members **39** coupled to each end of the operation rod **38** by way of a pin **38a**, and a biasing member **40** including a tension coil spring. The drive motor **37** is fixed to a fixing frame **41** of the gripping section **31**. The operation member **39** is coupled to the pair of gripping nails **33**, and is supported by the fixing frame **41** in a state movable in the front-back direction with the gripping nails **33**. A long hole **39a**, which is long in the left-right direction, is formed in the operation member **39**, and the pin **38a** is engaged with the long hole **39a**. The biasing member **40** biases the gripping nail **33** on the front side and the operation member **39** backward, and biases the gripping nail **33** on the back side and the operation member **39** forward.

Therefore, the pair of gripping nails **33** are biased in a direction of approaching each other by the biasing member **40**, and the specimen plate **10** can be gripped by the biasing force. When the operation rod **38** is turned by the drive motor **37**, the pair of gripping nails **33** and the operation member **39** move in a direction of separating from each other, thus opening the pair of gripping nails **33**. Thus, if the specimen plate **10** is gripped by the biasing force of the biasing member **40**, the specimen plate **10** can be continuously gripped without being dropped even if current flow to the drive motor **37** is stopped while gripping the specimen plate **10**.

As shown in FIG. **4**, the up-down moving section **32** includes a belt conveyor extending in the up-down direction, which belt conveyor **32** includes a pair of upper and lower pulleys **43** arranged on the supporting frame **35**, a belt **44** wound around the pulleys **43**, and a drive motor **45** for rotatably driving one pulley **43**. The gripping section **31** is coupled to the belt **44**. The gripping section **31** can be moved in the up-down direction by sending the belt **44** with the drive motor **45**. The up-down moving section **32** is not limited to the belt conveyor, and other configurations such as the chain transportation mechanism, the expansion/contraction operation mechanism including the fluid pressure cylinder, and the like may be adopted.

The vertical transport mechanism **22** transports the specimen plate **10** gripped by the gripping section **31** in the up-

8

down direction at the specimen transfer position **W** described above, and positions the specimen plate **10** to at least three heights, the upper position **H**, the middle position **M**, and the lower position **L**. The cassette transport mechanism **21** described above is arranged at the middle position **M**, the specimen plate **10** is removed from the cassette **11** by moving to the upper position **H** the specimen plate **10** in the cassette **11** transported by the cassette transport mechanism **21** while being gripped with the gripping section **31**. The horizontal transport mechanism **23**, to be described later, is arranged at the lower position **L**, the specimen storage device **20** is arranged at the middle position **M**, and the vertical transport mechanism **22** can also transfer the sample plate **10** with the mechanism **23** and the device **20**.

As described above, the vertical transport mechanism **22** merely transports the specimen plate **10** in the up-down direction at the specimen transfer position **W** and does not transport the specimen plate **10** in the front-back direction or the left-right direction. Therefore, taking out of the specimen plate **10** from the cassette **11**, the transfer of the specimen plate **10** with respect to the horizontal transport mechanism **23**, to be described later, and the delivery of the specimen plate **10** to the rack **12** transported by the rack transport mechanism **24** are all carried out by the up-down transportation of the specimen plate **10**. Thus, the configuration of the vertical transport mechanism **22** can be simplified, and the transportation distance (transportation range) of the specimen plate **10** in a non-protected (non-covered) state can be made as short as possible.

[Configuration of Horizontal Transport Mechanism **23**]

As shown in FIG. **1**, the horizontal transport mechanism **23** transports the specimen plate **10** in the left-right direction between the specimen transfer position **W** and a specimen transfer section **4e** of the specimen imaging apparatus **4**.

The horizontal transport mechanism **23** includes a transportation unit **50** for receiving the specimen plate **10** from the gripping section **31** at the specimen transfer position **W** and transporting the same in the left direction toward the specimen transfer section **4e** (see FIG. **1**) of the specimen imaging apparatus **4**, and receiving the specimen plate **10** performed with imaging from the specimen transfer section **4e** and transporting the same in the right direction toward the specimen transfer position **W**.

FIG. **6** is a plan view showing the transportation unit **50** of the horizontal transport mechanism **23**, FIG. **7** is a cross-sectional view taken along line VII-VII of FIG. **6**, FIGS. **8A** and **8B** are cross-sectional views taken along line VIII-VIII of FIG. **6** and are explanatory views showing an operation of a positioning mechanism of the specimen plate **10**.

The transportation unit **50** includes base **51**, a transportation case **52**, and a lateral transport section **53**. The base **51** is supported to be movable in the left-right direction between the specimen transfer position **W** and the specimen transfer section **4e** in the specimen imaging apparatus **4** shown in FIG. **1** by the apparatus frame of the specimen transporter **3**. The lateral transport section **53** includes a belt conveyor, and includes a belt **55** wound around a pair of left and right pulleys **54**, a drive motor **56** for driving one pulley **54**, and the like. A pair of left and right supporting pieces **51a** are arranged at the upper part of the base **51**, and a supporting shaft **57** having a shaft center in the left-right direction is bridged between the supporting pieces **51a**.

The transportation case **52** includes a first wall member **58**, a second wall member **59**, and a partitioning member **60**. As shown in FIG. **7** and FIGS. **8A** and **8B**, the first wall member **58** is bent to a horseshoe-shaped cross-section, and includes left and right side wall portions **58a**, **58b**, and an upper wall

portion 58c. The second wall member 59 includes a lower wall portion 59a opposing at the lower side of the upper wall portion 58c. The partitioning member 60 is arranged at the middle in the left and the right direction of the lower wall portion 59a. A bottom wall portion 58d bent toward the lower side is arranged at the front end portion of the first wall member 58. Therefore, the transportation case 52 is formed with two spaces 61, 62, which are surrounded by the first wall member 58, the second wall member 59, and the partitioning member 60 and opened toward the back side, arranged side by side on the left and the right. Such spaces configure a container where the specimen plate 10 can be contained.

The containers 61, 62 formed in the transportation case 52 include a first container 61 that contains the specimen plate 10 of before being performed with imaging and a second container 62 that contains the specimen plate 10 of after being performed with imaging. The specimen plate 10 is in a state the majority including the sample smearing 10a portion is covered by the transportation case 52 and the portion printed with the sample information 10b is projected out from the transportation case 52 when contained in the first and second containers 61, 62. Furthermore, as shown in FIG. 6, a cutout 63 is formed at a boundary portion of the side wall portion 58a, 58b and the upper wall portion 58c, and the bottom wall portion 58d in the first wall member 58. The cutout 63 serves as an opening for dropping attachments such as immersion oil, and the like, to be described later.

The first wall member 58 and the second wall member 59 of the transportation case 52 are coupled to be relatively movable in the left-right direction. Thus, the dimensional adjustment can be made to a state in which the left-right width w1 of the first container 61 is small and the left-right width w2 of the second container 62 is large, as shown in FIG. 8A, and a state in which the left-right width of the first container 61 is large and the left-right width of the second container 62 is small, as shown in FIG. 8B. In a state in which the left-right widths w1, w2 of the first and second containers 61, 62 are small, the gap between the specimen plate 10 and the left and right side wall portions 58a, 58b and the partitioning member 60 becomes small, so that the rattling in the left-right direction of the specimen plate 10 is suppressed. In a state in which the left-right widths w1, w2 of the first and second containers 61, 62 are wide, the gap between the specimen plate 10 and the left and right side wall portions 58a, 58b and the partitioning member 60 becomes large, and the insertion of the specimen plate 10 with respect to each container 61, 62 is facilitated. A method for adjusting the left-right widths w1, w2 of the first and second containers 61, 62 will be described later.

As shown in FIG. 6 and FIG. 7, a leg member 64 extending in the left-right direction is bridged over the lower end portions of the left and right side wall portions 58a, 58b in the first wall member 58. A coupling arm 59b extending toward the front side is arranged on both left and right sides of the second wall member 59. The distal end of the coupling arm 59b is coupled to the supporting shaft 57 in a freely turning manner. Therefore, the transportation case 52 can be swung up and down (forward and backward) with the supporting shaft 57 as the center, and the swinging enables the posture to be changed to a horizontal posture (reference posture) in which the openings of the first and second containers 61, 62 are directed toward the back side, and a standing posture in which the openings are directed toward the upper side.

The transportation case 52 of the transportation unit 50 has the posture changed by a posture changing mechanism 65. The posture changing mechanism 65 includes an operation bar 65a inserted to the lower side of the transportation case 52

of the transportation unit 50 positioned at the specimen transfer position W, and a drive section 65b (see FIGS. 9A to 9C) for moving the operation bar 65a up and down. The drive section 65b can be configured from a drive motor, a link member, and the like. When the operation bar 65a is moved by the drive section 65b, the transportation case 52 is swung up and down with the supporting shaft 57 as the supporting point to take either the horizontal posture or the standing posture. A biasing member 66 including a torsion coil spring is attached to the supporting shaft 57, and the biasing member 66 biases the transportation case 52 in a direction of swinging to the lower side (direction to become the horizontal posture). Furthermore, as shown in FIG. 7, a supporting section 67 including a magnet (suction member) 67a is arranged at the back part of the base 51, and the leg member 64 coupled to the first wall member 58 is mounted on the supporting section 67 and suctioned to the magnet 67a when the transportation case 52 takes the horizontal posture. The transportation case 52 is thus held in the horizontal posture so as not to lift up by vibration, and the like.

As described with reference to FIG. 3, the specimen plate 10 removed from the cassette 11 by the vertical transport mechanism 22 is positioned at the upper position H of the specimen transfer position W while being gripped by the gripping section 31. As shown in FIG. 4, the specimen plate 10 is transferred to the transportation case 52 of the transportation unit 50 at the lower position L of the specimen transfer position W. In this case, the transportation case 52 is caused to be in the standing posture by the posture changing mechanism 65, and the specimen plate 10 is inserted to the first container 61 of the transportation case 52 by lowering the gripping section 31.

FIGS. 9A to 9C and FIGS. 10A and 10B are schematic plan views describing the operation of the horizontal transport mechanism 23.

As shown in FIGS. 9A to 9C, the specimen plate 10 is inserted to the transportation case 52 of the transportation unit 50 at the specimen transfer position W, and when the posture of the transportation case 52 is changed to the horizontal posture by the posture changing mechanism 65, the lateral transport section 53 (see FIG. 6) is activated to transport the transportation case 52 in the left direction (arrow x4). The transportation case 52 is thereby positioned at the specimen transfer section 4e of the specimen imaging apparatus 4 (see FIG. 9A).

The specimen imaging apparatus 4 includes a transporting section 4f for transporting the specimen plate 10, and the transporting section 4f takes out the specimen plate 10 from the transportation case 52 transported to the specimen transfer section 4e (see FIG. 9B). The specimen plate 10 that is taken out is transported to the imaging section 4a (see FIG. 1) by the transporting section 4f, and the image of the sample is imaged by the imaging section 4a and provided for analysis. The specimen plate 10 performed with imaging (tested) is returned to the specimen transfer section 4e by the transporting section 4f, and returned to the transportation case 52 in standby.

In this case, the specimen plate 10 performed with imaging is inserted to the second container 62 of the transportation case 52 (see FIG. 9C). The transportation case 52 is then transported in the right direction (arrow x6) (see FIG. 10A), and again positioned at the specimen transfer position W. Thereafter, the posture of the transportation case 52 of the transportation unit 50 is changed from the horizontal posture to the standing posture by the posture changing mechanism 65 (see FIG. 10B).

11

In the operation of the horizontal transport mechanism 23 described above, if the specimen plate 10 to perform the analysis next is supplied to the vertical transport mechanism 22 while analysis is being performed on the specimen plate 10 transported to the specimen imaging apparatus 4, the transportation case 52 is transported from the specimen transfer section 4e to the specimen transfer position W, and the specimen plate 10 to perform the analysis next is contained in the first container 61 of the transportation case 52. Then, the transportation case 52 is positioned at the specimen transfer section 4e of the specimen imaging apparatus 4 by the operation of the lateral transport section 53, and the transporting section 4f takes out the specimen plate 10 to perform the analysis next from the first container 61. The specimen plate 10, which is transported the previous time and which imaging by the specimen imaging apparatus 4 is completed, is then contained in the second container 62 of the transportation case 52. Thus, the operation of taking out the specimen plate 10 to perform the imaging next from the transportation case 52 and the operation of returning the specimen plate 10 performed with imaging to the transportation case 52 can be simultaneously carried out in the specimen transfer section 4e by operating the horizontal transport mechanism 23. The specimen plate 10 thus can be efficiently transported, and the processing ability of the specimen transporter 3 and the specimen testing system 1 can be enhanced.

As described above, the horizontal transport mechanism 23 of the specimen transporter 3 transports the specimen plate 10 taken out from the cassette 11 to the specimen imaging apparatus 4 while being contained in the transportation case 52. Thus, the specimen plate 10 taken out from the cassette 11 is thus covered by the transportation case 52, whereby attachment of dust and the like during the transportation can be prevented. The transportation case 52 of the horizontal transport mechanism 23 separately includes the first container 61 that contains the specimen plate 10 of before being performed with imaging and the second container 62 that contains the specimen plate 10 of after being performed with imaging. Thus, the liquid such as the immersion oil that attached to the specimen plate 10 during the imaging may attach to the second container 62 but will not attach to the first container 61. Thus, the liquid can be prevented from attaching to the specimen plate 10 of before the imaging.

Since an opening (cutout 63, see FIG. 6) is formed at the bottom wall portion 58d of the transportation case 52, the liquid attached to the specimen plate 10 drops to the lower side through the opening and discharged to the outside of the transportation case 52, when the specimen plate 10 performed with imaging is transported to the specimen transfer position W and the transportation case 52 is made to a standing state. As shown in FIG. 7, FIG. 9, and FIG. 10, a liquid receiving tray 68 is arranged at the lower part of the specimen transfer position W, and the attachment of the liquid to other components in the specimen transporter 3, and the like can be prevented by receiving the liquid dropped from the transportation case 52. The liquid receiving tray 68 is attachable/detachable from the apparatus frame of the specimen transporter 3, so that the liquid accumulated on the liquid receiving tray 68 can be easily discarded and the liquid receiving tray 68 can be easily washed by detaching the liquid receiving tray 68. As shown in FIG. 9 and FIG. 10, a liquid receiving plate 69 is arranged on the lower side of the transportation path of the transportation case 52, so that the liquid dropped from the moving transportation case 52 can be received by the liquid receiving plate 69.

The transportation case 52 can contain two specimen plates 10 in a state arranged side by side on the left and the right, and

12

thus the structure can be miniaturized as much as possible. When the transportation case 52 is in the horizontal posture, the height of the specimen plate 10 contained in each container 61, 62 may be made the same, and the transfer height of the specimen plate 10 of before being performed with imaging and after being performed with imaging by the transporting section 4f of the specimen imaging apparatus 4 can be made constant. When the transportation case 52 is in the standing posture, the front-back position of the specimen plate 10 contained in each container 61, 62 may be made the same, and hence the front-back positions of specimen transfer by the gripping section 31 of the vertical transport mechanism 22 can be made constant.

As shown in FIG. 4, when the specimen plate 10 is inserted to the first container 61 of the transportation case 52 by the vertical transport mechanism 22, the left-right width of the first plate container 61 is in a wide state (see FIG. 8B). Thus, the specimen plate 10 can be inserted into the first container 61 with a margin without colliding. However, if the transportation case 52 is transported up to the specimen imaging apparatus 4 in this state, the specimen plate 10 becomes shaky in the first container 61 thus possibly affecting the subsequent transfer of the specimen plate 10. Therefore, in the present embodiment, the transportation case 52 is once moved in the right direction (arrow x3) to make contact with the wall 71 of the apparatus frame before transporting the specimen plate 10 to the specimen imaging apparatus 4, as shown in FIG. 9A. More specifically, as shown in FIG. 8A, the first wall member 58 is moved toward the right side in the figure vis-a-vis to the second wall member 59 by bringing the leg member 64 into contact with the wall 71. The left-right width w1 of the first container 61 thus becomes small, and the rattling of the specimen plate 10 can be eliminated. In this case, the left-right width w2 of the second container 62 becomes relatively large.

The specimen plate 10 performed with imaging is inserted to the second container 62 in the transportation unit 50 by the transporting section 4f in the specimen transfer section 4e of the specimen imaging apparatus 4. In this case, the left-right width w2 of the second container 2 is large, and thus the specimen plate 10 performed with imaging can be inserted to the second container 62 with a margin without colliding. However, if the specimen plate 10 performed with imaging 10 is transported to the specimen transfer position W as it is, the specimen plate 10 may possibly become shaky. Therefore, in the present embodiment, the transportation case 52 is once moved in the left direction (arrow x5) shown in FIG. 10A to make contact with the wall 72 of the apparatus frame before transporting the specimen plate 10 to the specimen transfer position W. More specifically, as shown in FIG. 8B, the first wall member 58 is moved toward the left side in the figure vis-a-vis to the second wall member 59 by bringing the leg member 64 into contact with the wall 72. The left-right width w2 of the second container 62 thus becomes small, and the rattling of the specimen plate 10 can be eliminated.

[Configuration of Specimen Storage Device 20]

The specimen storage device 20 (rack transport mechanism 24, accumulating section 75) is provided to store in the predetermined rack 12, the specimen plate 10 performed with imaging transported to the specimen transfer position W by the horizontal transport mechanism 23 as described above. As shown in FIG. 11 to FIG. 14, the rack 12 has a bottom wall 13a of a rectangular shape in plan view and four side walls 13b, 13c raised toward the upper side from each side of the bottom wall 13a, and has a shape in which the upper side is opened. A total of 12 specimen plates 10 can be stored inside the rack 12. Specifically, the rack 12 can store a plurality of specimen

13

plates **10** so as to be lined in the longitudinal direction of the bottom wall **13a** in a substantially perpendicularly standing posture.

A recessed groove (supporting section) **14** extending in the up-down direction is formed in plurals on the front and back on the inner side of the left and right side walls **13b** of the rack **12**. The specimen plate **10** is supported in the standing posture, and a plurality of specimen plates **10** are stored with a spacing without contacting each other by fitting both side portions of the specimen plate **10** to the recessed groove **14**. The recessed groove **14** is formed such that the width becomes wider toward the upper side. Thus, when fitting the specimen plate **10** to the recessed groove **14**, the specimen plate **10** is less likely to hit the projecting portion between the recessed grooves **14**, and the rattling can be suppressed by inserting the specimen plate **10** to the lower side of the recessed groove **14**.

Furthermore, the liquid such as the immersion oil, and the like that attached in imaging flows toward the lower side and is accumulated at the bottom wall **13a** of the rack **12** since the specimen plate **10** is stored in a standing state. Thus, the liquid does not spill out to the outside or get the moving region of the rack **12**, and the like dirty. A recess **13d** is formed at the lower end side of the left and right side walls **13b**, and the contacting area with respect to the bottom plate **80** of the accumulating section **75**, to be described later, is reduced by the recess **13d**. The resistance of when the rack **12** slidably moves on the bottom plate **80** is thus reduced.

A hook portion **15** bent toward the lower side is formed at the upper end portion of the front and back side walls **13c** of the rack **12**. The rack **12** is formed to be plane symmetric with respect to a perpendicular plane passing through the front-back center line **01** and plane symmetric with respect to a perpendicular plane passing through the left-right center line **02** in the plan view of FIG. **12**. In other words, the rack **12** is formed to be rotation symmetric (dyad symmetric) with respect to the central line **C** extending in the up-down direction of the rack **12** in plan view. Therefore, when setting the rack **12** with respect to the accumulating section **75** of the specimen transporter **3**, the rack can be set without taking the direction of the front-back direction into consideration.

As shown in FIG. **13**, a recess **17** is formed on both left and right sides of the lower end portion in the front and back side walls **13c** of the rack **12**. A portion between the recesses **17** on both left and right sides is a detected portion **16** to be detected by a sensor (detector) for detecting whether or not the rack **12** exists at a predetermined position (take-out collecting position R) in the accumulating section **75**, to be described later.

As shown in FIG. **1**, the specimen storage device **20** includes the accumulating section **75** capable of accumulating a plurality of racks **12** so as to be lined in the left-right direction, and the rack transport mechanism **24** for transporting the rack **12** in the horizontal direction at the inside and the outside of the accumulating section **75**. The rack transport mechanism **24** includes a lateral transport section **76** (see FIG. **15**) for transporting the rack **12** in the left-right direction, and a longitudinal transport section **77** for transporting the rack **12** in the front-back direction from the predetermined position R in the accumulating section **75**. The accumulating section **75** is arranged on the front side of the specimen transfer position W, and the longitudinal transport section **77** is arranged to transverse the specimen transfer position W in the front-back direction.

FIG. **15** is a cross-sectional explanatory view of the rack transport mechanism **24** seen from the side, and FIG. **16** and FIG. **17** are cross-sectional explanatory views of the rack transport mechanism **24** seen from the front.

14

The accumulating section **75** includes the bottom plate **80** formed to a rectangular shape that is long in the left-right direction in plan view, and front and back plates **81**, **82** and left and right plates **83** raised from the four sides of the bottom plate. A plurality of racks **12** is mounted on the bottom plate **80** to accumulate the same. The accumulating section **75** of the present embodiment has the take-out collecting position R of the rack **12** set at a central part in the left-right direction. At the take-out collecting position R, the rack **12** is taken out from the accumulating section **75**, and the specimen plate **10** is stored with respect to the rack **12**. The rack **12** in which the storing of the specimen plate **10** is completed is again returned to the take out collecting position R.

A pre-stage accumulating section (second accumulating section) **75A** for accumulating an empty rack **12**, in which the specimen plate **10** is not stored, is arranged on the right side of the take-out collecting position R in the accumulating section **75**, and a post-stage accumulating section (first accumulating section) **75B** for accumulating the rack **12**, in which the specimen plate **10** performed with imaging (tested) is stored, is arranged on the left side of the take-out collecting position R.

As shown in FIG. **16**, the back plate **82** of the accumulating section **75** is formed only at the portions of the pre-stage accumulating section **75A** and the post-stage accumulating section **75B**, and is not arranged at the take-out collecting position R. Thus, the rack **12** arranged at the take-out collecting position R can be pulled out toward the back side. Furthermore, as shown in FIG. **15**, the hook portion **15** on the back side of the rack **12** contained in the pre-stage accumulating section **75A** and the post-stage accumulating section **75B** is engaged with the upper end portion of the back plate **82**. Thus, the overturning in the left-right direction of the rack **12** in the accumulating sections **75A**, **75B** is prevented. Therefore, the hook portion **15** formed on the rack **12** and the back plate **82** of the accumulating sections **75A**, **75B** function as an overturn preventing mechanism for preventing the overturning of the rack **12**.

The lateral transport section **76** is configured to transport the rack **12** in the accumulating section **75** to the right and the left. In other words, the lateral transport section **76** transports the rack **12** from the pre-stage accumulating section **75A** to the post-stage accumulating section **75B** through the take-out collecting position R. More specifically, the lateral transport section **76** includes a pusher member **85** that engages a rack **12** at the right most side (back part side in the transporting direction) among the plurality of racks **12** contained in the pre-stage accumulating section **75A**, and a drive section **86** for moving the pusher member **85** in the left-right direction.

As shown in FIG. **15**, a pair of front and back pusher members **85** are arranged, and can engage the front end portion and the back end portion of the rack **12**, respectively. The pair of front and back pusher members **85** are coupled by a coupling member **87** at the lower side of the accumulating section **75**, and the movement in the left-right direction of the coupling member **87** is guided by a guide rail **88** extending in the left-right direction.

As shown in FIG. **16** and FIG. **17**, the drive section **86** is configured by a belt conveyor. Specifically, the drive section **86** includes a pair of left and right pulleys **86a**, a belt **86b** wound around the pulleys **86a**, and a drive motor **86c** for driving one pulley **86a**. The coupling member **87** is coupled to the belt **86b**.

When the belt **86b** is sent by the operation of the drive motor **86c**, the pusher member **85** moves in the left-right direction through the coupling member **87**. All the racks **12** on the accumulating section **75** can be moved in the left direction

15

by engaging the pusher member **85** with the rack **12** on the right most side and moving the same in the left direction. As shown in FIG. **16**, the pusher member **85** has the right end portion of the pre-stage accumulating section **75A** as an initial position, and can move the rack **12** by moving in the left direction from the initial position.

The rack **12** transported to the take-out collecting position R by the lateral transport section **76** is taken out from the accumulating section **75** by the longitudinal transport section **77**, to be described later, and a stopper mechanism **78** for stopping the transportation so that the rack **12** existing other than at the take-out collecting position R does not enter the take-out collecting position R by mistake is arranged.

As shown in FIG. **16** and FIG. **17**, at both left and right sides of the take-out collecting position R, the stopper mechanism **78** includes a transportation stopping member **90** that projects out on the bottom plate **80** of the accumulating section **75** to act on the rack **12**, and a switching section **91** for switching between an acting state in which the transportation stopping member **90** projects out from the bottom plate **80** and a non-acting state in which the transportation stopping member **90** is evacuated to the lower side of the bottom plate **80**. As shown in FIG. **15**, two transportation stopping members **90** are arranged in a front and back manner at each of the left and the right of the take-out collecting position R.

Each transportation stopping member **90** is turnably attached about a supporting shaft **90a** in the front-back direction at the lower side of the bottom plate **80**. The transportation stopping members **90** facing each other in the left-right direction are coupled by a link member **90b** to swing in cooperation. Specifically, the left and right transportation stopping members **90** are evacuated from the bottom plate **80** by being swung in a direction of approaching each other, and are projected out on the bottom plate **80** by being swung in a direction of separating from each other.

The switching section **91** includes a drive link **91a** having one end coupled to a lower end portion of the transportation stopping member **90** on the right side, and an interlocking link **91b** having one end coupled to the other end of the drive link **91a**. The interlocking link **91b** has a central part turnably attached about a supporting shaft **91c** in the front-back direction, and the drive link **91a** is coupled to the upper end portion. An engagement member **87a** that moves with the coupling member **87** of the lateral transport section **76** is engaged with the lower end portion of the interlocking link **91b**. Furthermore, the interlocking link **91b** is biased in a clockwise direction by a biasing member (not shown).

Therefore, the stopper mechanism **78** operates in cooperation with the operation of the lateral transport section **76**. Specifically, as shown in FIG. **16**, when the pusher member **85** is at the initial position on the right end, the engagement member **87a** engages the interlocking link **91b** and the transportation stopping member **90** is in the acting state of projecting out from the bottom plate **80**. In this state, the racks **12** in the pre-stage accumulating section **75A** and the post-stage accumulating section **75B** cannot enter the take-out collecting position R. The rack **12** also cannot move to the take-out collecting position R since the pusher member **85** is at the initial position.

As shown in FIG. **17**, when the pusher member **85** is moved in the left direction from the initial position to push the rack **12**, the engagement member **87a** is disengaged from the interlocking link **91b** so that the transportation stopping member **90** is in the non-acting state through the drive link **91a**. Therefore, the rack **12** pushed by the pusher member **85** can be transported in the accumulating section **75** without being stopped by the transportation stopping member **90**.

16

Thus, the stopper mechanism **78** (transportation stopping member **90**) operates in cooperation with the lateral transport section **76**, and is driven by the same drive section as the drive section **86** of the lateral transport section **76**. Therefore, the structure can be simplified compared to when driving the relevant components with separate drive sections.

FIG. **21** is a side explanatory view showing the longitudinal transport section **77** (retreated state) of the rack transport mechanism **24**, and FIG. **22** is a side explanatory view showing the longitudinal transport section **77** (advanced state) of the rack transport mechanism **24**.

The longitudinal transport section **77** has a function of taking out the rack **12** at the take-out collecting position R from the accumulating section **75** by moving it backward by the longitudinal transport section **77**, transporting the rack **12** to a storage position of the specimen plate **10** (specimen transfer position W described above), and again returning the rack **12** of after being stored with the specimen plate **10** back to the accumulating section **75**.

The longitudinal transport section **77** includes a supporting section **92** for supporting the rack **12**, and a drive section **94** for moving the supporting section **92** in the front-back direction. The supporting section **92** includes an engagement nail **93** for engaging the hook portion **15** on the back side of the rack **12**, a posture holder **95** for holding the posture of the rack **12** engaged to the engagement nail **93**, and a movement member **96** having the engagement nail **93** and the posture holder **95** attached to the front end.

The movement member **96** is a long member formed to be long in the front-back direction, and is supported to be movable in the front-back direction by a guide section **97**.

The drive section **94** includes a belt conveyor, and includes a pair of front and back pulleys **94a**, a belt **94b** wound around the pulleys **94a**, and a drive motor **94c** for driving one pulley **94a**. A back end portion of the movement member **96** is coupled to the belt **94b**. Therefore, the engagement nail **93** and the posture holder **95** can be moved in the front-back direction through the movement member **96** by the operation of the drive motor **94c**. The position of the engagement nail **93** shown in FIG. **21** is a most retreated initial position.

The engagement nail **93** supports the rack **12** in a lifted state by engaging with the hook portion **15** on the back side of the rack **12**. The front portion side of the rack **12** tilts downward if the engagement nail **93** is merely engaged with the hook portion **15**, and hence the posture of the rack **12** is held horizontal by bringing the posture holder **95** into contact with the back side wall **13c** of the rack **12**. The posture holder **95** includes a holder main body **95a** that makes contact with the rack **12**, and an operation member **95c** swingably arranged about a supporting shaft **95b** in the left-right direction on the movement member **96**. The operation member **95c** is biased to swing toward the front side by a biasing member **95d** including a tension coil spring bridged between the operation member **95c** and the engagement nail **93**.

FIG. **22** shows a state in which the engagement nail **93** and the posture holder **95** are advanced toward the front side the most by the longitudinal transport section **77**. In this case, the engagement nail **93** is arranged at a position lined in the left-right direction with the upper end portion of the back plate **82** of the accumulating section **75**. Therefore, when the rack **12** is transported to the take-out collecting position R by the lateral transport section **76**, the hook portion **15** on the back side thereof automatically engages with the engagement nail **93**. The operation member **95c** of the posture holder **95** makes contact with a contacting portion **98** arranged on the upper back side of the accumulating section **75** so as to be swung toward the back side. Thus, the holder main body **95a**

17

of the posture holder **95** is in a state retreated from the back side wall **13c** of the rack **12** so as not to stop the lateral transportation of the rack **12**. A roller **96a** is attached to the lower surface of the front end portion of the movement member **96**, and the roller **96a** is mounted on a supporting board **99** arranged on the lower back side of the accumulating section **75**. The front end portion of the movement member **96** is thereby supported, so that the engagement nail **93** is positioned at an appropriate position in the up-down direction.

FIGS. **18A** to **18C** to FIGS. **20A** and **20B** are schematic plan views describing the operation of the lateral transport section **76** of the rack transport mechanism **24**.

FIG. **18A** shows a state in which five empty racks **12** are accumulated in the pre-stage accumulating section **75A**. Whether or not there is a rack **12** in the pre-stage accumulating section **75A** can be detected with a sensor **100**. The sensor **100** is configured by a pair of light projecting/receiving units having an optical axis that diagonally passes the pre-stage accumulating section **75A**. The pusher member **85** of the lateral transport section **76** is arranged at the initial position on the right end. Furthermore, whether or not there is a rack **12** in the post-stage accumulating section **75B** can be detected with a sensor **102**. The sensor **102** is configured by a reflective light projecting/receiving unit arranged at the left end of the post-stage accumulating section **75B**. When the rack **12** is transported to the left end of the post-stage accumulating section **75B**, that is, when the post-stage accumulating section **75B** becomes full, the light signal reflected by the rack **12** at the left end is received by the sensor **102** thus detecting that the post-stage accumulating section **75B** is full.

In FIG. **18B**, when the pusher member **85** is automatically moved in the left direction, all the racks **12** in the pre-stage accumulating section **75A** are pushed in the left direction. The operation of the pusher member **85** is stopped when the rack **12** at the most left side is positioned at the take-out collecting position **R**. In this case, the hook portion **15** (see FIG. **22**) of the rack **12** positioned at the take-out collecting position **R** engages with the engagement nail **93** of the longitudinal transport section **77** waiting at the relevant position **R**.

Whether or not the rack **12** is positioned at the take-out collecting position **R** may be detected with a sensor **101**. As shown in FIG. **15**, the sensor **101** includes a pair of light projecting/receiving units having an optical axis **101a** that passes through holes **81a**, **80a** formed in the front plate **81** and the bottom plate **80** of the accumulating section **75**, respectively. The sensor **101** can detect that the rack **12** is positioned at the take-out collecting position **R** when the optical axis **101a** is shielded by a detected portion **16** formed at the lower end portion of the front side wall **13c** of the rack **12**. In other words, as shown in FIG. **13**, the existence of the rack **12** is not detected if the optical axis **101a** of the sensor **101** is in a range **A** (non-detecting region) of the recesses **17** of the rack **12** lined side by side to the left and right, and the existence of the rack **12** is detected if the optical axis **101a** is in a range **B** (detecting region) of the detected portion **16**. Thus, the detecting region **B** and the non-detecting region **A** are alternately arranged when the plurality of racks **12** are lined to the left and the right, so that each rack **12** can be reliably detected by the sensor **101**.

Thereafter, as shown in FIG. **18C**, the rack **12** is taken out from the take-out collecting position **R** when the engagement nail **93** of the longitudinal transport section **77** is moved toward the back side. The specimen plate **10** performed with imaging is sequentially stored in the rack **12** taken out. The details of such operation will be described later.

As shown in FIG. **19A**, when the pusher member **85** is automatically moved in the right direction and positioned at

18

the initial position, the transportation stopping member **90** projects out on the bottom plate **80** of the accumulating section **75**. The racks **12** remaining in the pre-stage accumulating section **75A** thus can be prevented from entering the take-out collecting position **R**. As shown in FIG. **19B**, when the rack **12** of after storing the specimen plate **10** is advanced forward by the longitudinal transport section **77** and returned to the take-out collecting position **R**, the pusher member **85** is slightly moved in the left direction and the transportation stopping member **90** is evacuated to the lower side of the bottom plate **80**. In the present embodiment, the longitudinal transport section **77** does not move the rack **12** to the take-out collecting position **R** when the transportation stopping member **90** is projecting out on the bottom plate **80**.

In FIG. **19A**, when the transportation stopping member **90** is projecting out on the bottom plate **80**, the rack **12** of the pre-stage accumulating section **75A** is slightly pushed back in the right direction. This is because the movement in the right direction is involved when the transportation stopping member **90** on the right side projects out from the bottom plate **80**, as shown in FIG. **16** and FIG. **17**. Wider space of the take-out collecting position **R** can be ensured and interference with another rack **12** in the accumulating section **75** can be prevented when the rack **12** of after storing the specimen plate **10** is returned to the take-out collecting position **R** by pushing back the rack **12** of the pre-stage accumulating section **75A** in the right direction.

Then, as shown in FIG. **19C**, the pusher member **85** at the initial position is further automatically moved in the left direction, and the four empty racks **12** in the pre-stage accumulating section **75A** and the rack **12** storing the specimen plate **10** at the take-out collecting position **R** are all moved in the left direction. When the empty rack **12** is positioned at the take-out collecting position **R**, the pusher member **85** stops the operation and the rack **12** is taken out toward the back side by the longitudinal transport section **77**, as shown in FIG. **20A**.

Thereafter, when the pusher member **85** is automatically returned to the initial position, the transportation stopping member **90** again projects out on the bottom plate **80**, as shown in FIG. **20B**. The racks **12** remaining in the pre-stage accumulating section **75A** and the rack **12** in the post-stage accumulating section **75B** thus can be prevented from entering the take-out collecting position **R**. In this case, the rack **12** storing the specimen plate **10** is slightly pushed in the left direction by the transportation stopping member **90**, and the empty rack **12** is pushed back slightly in the right direction by the transportation stopping member **90**, so that a wide space of the take-out collecting position **R** can be ensured.

The operation of storing the specimen plate **10** performed with imaging in the rack **12** will now be described.

FIGS. **23A** to **23C** are schematic side views describing the operation of the longitudinal transport section **77** of the rack transport mechanism **24**. In FIG. **23A**, the rack **12** taken out from the take-out collecting position **R** of the accumulating section **75** is positioned on the back side than the specimen transfer position **W** by retreating the engagement nail **93** of the longitudinal transport section **77** to the initial position. As described above, when the vertical transport mechanism **22** takes out the specimen plate **10** performed with imaging from the transportation case **52** in the horizontal transport mechanism **23** (see FIG. **10B**) and transports the same to the upper position **H** of the specimen transfer position **W**, the longitudinal transport section **77** of the rack transport mechanism **24** moves the rack **12** forward (arrow **y1**) and positions the same on the lower side of the gripping section **31**.

19

As shown in FIG. 12, the rack 12 includes a storage space of the specimen plate 10 at a plurality of areas in the front-back direction, so that the longitudinal transport section 77 moves the rack 12 forward to align a predetermined storage space, to which the specimen plate 10 is to be inserted, at the lower side of the specimen plate 10.

Then, as shown in FIG. 23B, the gripping section 31 in the vertical transport mechanism 22 is lowered and the specimen plate 10 is automatically inserted into the rack 12.

Thereafter, as shown in FIG. 23C, the gripping section 31 is raised with the gripping nail 33 of the gripping section 31 opened. The rack 12 is moved toward the back side (arrow y2) by the longitudinal transport section 77 when successively storing the specimen plate 10 in the rack 12, and the rack 12 is further moved forward (arrow y3) by the longitudinal transport section 77 so that the rack 12 is returned to the take-out collecting position R in the accumulating section 75 when the operations after FIG. 23A are repeated and the storing of the specimen plate 10 with respect to the rack 12 is finished.

As shown in FIG. 19C and FIG. 20A, when the rack 12 is returned to the accumulating section 75, a new empty rack 12 is taken out from the accumulating section 75 and the operations after FIG. 23A are again repeatedly carried out.

The rack transport mechanism 24 of the present embodiment sets a plurality of racks 12 so as to be lined in the left-right direction in the accumulating section 75 with the longitudinal direction of the rack 12 (direction in which the specimen plates 10 are lined) directed in the front-back direction, and transports the rack 12 in the left-right direction in the relevant accumulating section 75. Thus, the accumulating section 75 of the rack transport mechanism 24 can be configured small in the left-right direction and the transportation distance in the left-right direction of the rack 12 by the lateral transport section 76 can also be reduced compared to when the longitudinal direction of the rack 12 is directed in the left-right direction.

The rack transport mechanism 24 can perform the operation of taking out and collecting the rack 12 with respect to the accumulating section 75 and the operation of aligning each storage position of the rack 12 at the standby position of the specimen plate 10 with the movement in one direction since the direction of taking out and collecting the rack 12 with respect to the accumulating section 75 and the direction in which the specimen plates 10 are lined in the rack 12 are coincided, whereby the configuration of the rack transport mechanism 24 can be simplified.

Furthermore, the rack transport mechanism 24 transports the rack 12 in the front-back direction toward a specimen storage position with the opening directed toward the upper side, so that the specimen plate 10 is inserted from the upper side to the rack 12 by the vertical transport mechanism 22 at the specimen storage position. The transportation distance of the specimen plate 10 thus becomes as short as possible by transporting the rack 12 itself, and the liquid such as the immersion oil, and the like can be suppressed from leaking out to the transportation path of the specimen plate 10.

The specimen storage device 20 of the present embodiment includes the pre-stage accumulating section 75A for accumulating a rack 12 that does not contain a specimen, and a post-stage accumulating section 75B for accumulating the rack 12 that contains the specimen plate 10 performed with imaging on the front portion side of the specimen transporter 3 (front side than the specimen transport mechanisms 21 to 23), so that the user can supply the rack 12 to the pre-stage accumulating section 75A and take out the rack 12 from the post-stage accumulating section 75B at one area on the front

20

side of the specimen transporter 3, whereby the operability of such operations can be enhanced.

If the rack 12 not stored with the specimen is accumulated in the pre-stage accumulating section 75A, exchange with the rack 12 stored with the specimen can be rapidly carried, whereby the operation efficiency can be enhanced. Furthermore, since the rack 12 stored with the specimen can be temporarily accumulated by arranging the post-stage accumulating section 75B, the next rack 12 not stored with the specimen can be moved to the specimen storage position without taking the rack 12 out from the specimen transporter 3.

The specimen testing system 1 of the present embodiment has the specimen transporter 3 arranged between the specimen creating apparatus 2 and the specimen imaging apparatus 4, and the specimen plate 10 created by the specimen creating apparatus 2 is not directly supplied to the specimen imaging apparatus 4 but is supplied through the specimen transporter 3. Furthermore, the specimen plate 10 performed with imaging is not collected at the specimen imaging apparatus 4, but is collected to the rack 12 at the specimen transporter 3. Thus, the specimen imaging apparatus 4 does not need to include a structure for receiving the specimen plate 10 from the specimen creating apparatus 2 and a structure for collecting the specimen plate 10 performed with imaging, and merely needs to include the transfer section 4e of the specimen with respect to transporter 3. The structure is thus simplified and miniaturized. Furthermore, since the specimen creating apparatus 2 also does not need to include a structure for transporting the specimen plate 10 to the specimen imaging apparatus 4, the structure can be simplified and miniaturized.

Furthermore, the specimen transporter 3 has a function of transporting the specimen plate 10 from the specimen creating apparatus 2 to the specimen imaging apparatus 4 and a function of collecting the specimen plate 10 performed with imaging in the specimen imaging apparatus 4, so that the system scale of the entire specimen testing system 1 can be reduced compared to when realizing such functions with separate apparatuses.

The specimen transporter 3 can collect the used cassette 11 and the specimen plate 10 performed with imaging, so that the user merely needs to take out and process the used cassette 11 and the specimen plate 10 performed with imaging only from the specimen transporter 3, whereby the operability of the processing can be enhanced.

In the specimen transporter 3 of the present embodiment, the transportation path for receiving the specimen plate 10 from the specimen creating apparatus 2 and transporting the specimen plate to the specimen imaging apparatus 4, and the transportation path for receiving the specimen plate 10 from the specimen imaging apparatus 4 and storing the specimen plate in the rack 12 are partially overlapped. In other words, the vertical transport mechanism 22 and the horizontal transport mechanism 23 transport the specimen plate 10 on both transportation paths. The structure of the specimen transporter 3 can be simplified and miniaturized by partially overlapping both transportation paths and transporting the specimen plate 10 with the common specimen transport mechanisms 22, 23 on the overlapping transportation path.

The specimen transport mechanisms 21 to 23 in the specimen transporter 3 transport the specimen plate 10 while transferring the specimen plate 10 with each other at the specimen transfer position W. Thus, with the specimen transfer position W as a reference, smooth transportation of the specimen plate 10 cooperating with each other can be achieved. The vertical transport mechanism 22 linearly transports the specimen

21

plate 10 in the up-down direction at the specimen transfer position W, so that the specimen plate 10 can be appropriately transferred with the cassette transport mechanism 21 and the horizontal transport mechanism 23 having different heights from each other. The vertical transport mechanism 22 also has a function of not only transferring the specimen plate 10 with the cassette transport mechanism 21 and the horizontal transport mechanism 23, but also storing the specimen plate 10 in the rack 12 transported by the rack transport mechanism 24, so that the specimen plate 10 can be appropriately transported between the horizontal transport mechanism 23 and the rack 12 having different heights from each other.

The present invention is not limited to the embodiment described above, and changes can be appropriately made within a scope of the invention described in the Claims.

For example, in the rack transport mechanism 24, the take-out collecting position R is set at one area in the accumulating section 75, but the take-out position and the collecting position may be individually provided. If the take-out position and the collecting position are individually provided, the stopper mechanism 78 may be arranged to both positions or the stopper mechanism 78 may be arranged to only one of the positions. The accumulating number of racks 12 in the accumulating section 75 also may be appropriately changed.

The supply of the specimen plate 10 to the specimen transporter 3 may be performed not only from the specimen creating apparatus 2 but may also be performed by hand on the specimen receiving section 26.

The sample to be tested is not limited to blood and may be urine or samples collected from the uterine cervix.

The specimen imaging apparatus (specimen testing apparatus) 4 may not perform operations from imaging to analysis of the specimen, and may perform up to acquisition of the image data by imaging and perform the analysis of the image data with another device or by humans.

What is claimed is:

1. A specimen storage device for storing a specimen plate in a rack, the specimen plate imaged by a specimen imaging apparatus, the specimen storage device comprising:

a specimen container transporter comprising a specimen container configured to contain a specimen plate and a specimen container transport mechanism configured to transport the specimen container between a first position and a second position for providing the specimen plate to the specimen imaging apparatus;

a specimen storage section comprising an accumulating section containing a plurality of racks and a rack transport mechanism configured to supply a selected rack among the plurality of racks accumulated in the accumulating section to a specimen storage position, each of the racks configured to store a plurality of specimen plates in an upright position and having an opening at an upper part; and

a specimen transport mechanism configured to insert the specimen plate into the specimen container at the first position and to take out the specimen plate from the specimen container at the first position,

wherein the specimen storage device further includes a controller that is configured to:

insert the specimen plate in the specimen container at the first position by the specimen transport mechanism;

transport the specimen container with the inserted the specimen plate from the first position to the second position by the specimen container transport mechanism;

provide the specimen plate to the specimen image apparatus for imaging;

22

receive the specimen plate imaged by the specimen imaging apparatus in the specimen container positioned at the second position from the specimen imaging apparatus; transport the specimen container containing the imaged specimen plate from the second position to the first position by the specimen container transport mechanism;

take out the imaged specimen plate from the specimen container at the first position by the specimen transport mechanism; and

insert the imaged specimen plate into the selected rack supplied at the specimen storage position by the specimen transport mechanism,

wherein the specimen storage position and the first position are the same position.

2. The specimen storage device according to claim 1, wherein the specimen transport mechanism transports the specimen plate in the up-down direction in the upright position.

3. The specimen storage device according to claim 1, wherein the rack transport mechanism transports the rack in a horizontal direction.

4. The specimen storage device according to claim 1, wherein the specimen transport mechanism comprises a holder configured to hold and release the specimen plate; and the specimen transport mechanism transports the holder holding the specimen plate to above the specimen storage position, then lowers the holder to store the specimen plate in the rack at the specimen storage position, and thereafter, releases the holder.

5. The specimen storage device according to claim 1, wherein the accumulating section comprises:

a first accumulating section configured to accumulate the rack stored with the specimen plate, wherein the rack transport mechanism transports the rack from the specimen storage position to the first accumulating section.

6. The specimen storage device according to claim 5, further comprising:

a first stopper mechanism configured to stop transportation of the rack between a collecting position, from which the rack is collected from the first accumulating section, and the first accumulating section, wherein the first stopper mechanism does not stop the transportation of the rack when the rack is at the collecting position.

7. The specimen storage device according to claim 6, further comprising:

a second accumulating section configured to accumulate the rack not stored with the specimen plate, wherein the rack transport mechanism transports the rack from the second accumulating section to the specimen storage position.

8. The specimen storage device according to claim 7, further comprising:

a second stopper mechanism configured to stop transportation of the rack between a take-out position, at which the rack is taken out from the second accumulating section, and the second accumulating section, wherein the second transportation stopper does not stop the transportation of the rack when the rack is at the take-out position.

9. The specimen storage device according to claim 8, wherein the take-out position and the collecting position are the same position.

10. The specimen storage device according to claim 1, further comprising:

an overturn preventing mechanism configured to prevent overturning of the rack.

23

11. The specimen storage device according to claim 1, further comprising:

a detector configured to detect a region on an outer wall surface of the rack.

12. The specimen storage device according to claim 11, wherein the detector is arranged on at least one of a collecting position, from which the rack is collected to a first accumulating section configured to accumulate a rack stored with a specimen plate, and a take-out position, at which the rack is taken out from a second accumulating section configured to accumulate a rack not stored with a specimen plate.

13. The specimen storage device according to claim 11, wherein the detector is arranged at a take-out collecting position, from which the rack is collected in a first accumulating section configured to accumulate a rack stored with a specimen plate and to which the rack is taken out from a second accumulating section configured to accumulate a rack not stored with a specimen plate.

14. The specimen storage device according to claim 1, wherein the rack has a rotation symmetric shape with a central line as a reference in a plan view.

15. A specimen storage device comprising:

a rack configured to store a plurality of specimen plates in an upright position and having an opening at an upper part and storing an imaged specimen plate;

a specimen container transporter comprising a specimen container configured to contain a specimen plate and a specimen container transport mechanism configured to transport the specimen container between a first position and a second position for providing the specimen plate to a specimen imaging apparatus;

a specimen storage section comprising an accumulating section containing a plurality of racks and a rack transport mechanism configured to supply a selected rack among the plurality of racks accumulated in the accumulating section to a specimen storage position; and

a specimen transport mechanism configured to insert the specimen plate into the specimen container at the first position and to take out the specimen plate from the specimen container at the first position,

wherein the specimen storage device further includes a controller that is configured to;

insert the specimen plate into the specimen container at the first position by the specimen transport mechanism;

transport the specimen container with the inserted specimen plate from the first position to the second position by the specimen container transport mechanism;

provide the specimen plate to the specimen image apparatus for imaging;

receive the specimen plate imaged by the specimen imaging apparatus in the specimen container positioned at the second position from the specimen imaging apparatus;

transport the specimen container containing the imaged specimen plate from the second position to the first position by the specimen container transport mechanism;

take out the imaged specimen plate from the specimen container at the first position by the specimen transport mechanism; and

insert the imaged specimen plate into the selected rack supplied at the specimen storage position by the specimen transport mechanism,

wherein the specimen storage position and the first position are the same position.

24

16. The specimen storage device according to claim 15, wherein the specimen transport mechanism transports the specimen plate in the up-down direction in the upright position.

17. The specimen storage device according to claim 15, wherein the rack transport mechanism transports the rack in a horizontal direction.

18. The specimen storage device according to claim 15, wherein the specimen transport mechanism comprises a holder configured to hold and release the specimen plate and the specimen transport mechanism transports the holder holding the specimen plate to above a specimen storage position, then lowers the holder to store the specimen plate in the rack at the specimen storage position, and thereafter, releases the holder.

19. A specimen storage device for storing a specimen plate imaged by a specimen imaging apparatus in a rack, the specimen storage device comprising:

a specimen container transporter comprising a set of first and second specimen containers and a specimen container transport mechanism configured to transport the set of specimen containers between a first position and a second position for providing the specimen plate to the specimen imaging apparatus;

a specimen storage section comprising an accumulating section containing a plurality of racks and a rack transport mechanism configured to supply a selected rack among the plurality of racks accumulated in the accumulating section to the first position, each of the racks being configured to store a plurality of specimen plates in an upright position and having an opening at an upper part; and

a specimen transport mechanism configured to insert the specimen plate into either of the first and second specimen containers at the first position and to take out the specimen plate from either of the first and second specimen containers at the first position,

wherein the specimen storage device further includes a controller that is configured to;

insert the specimen plate to the first specimen container at the first position by the specimen transport mechanism; transport the set of specimen containers from the first position to the second position by the specimen container transport mechanism so as to position the first specimen container with the inserted specimen plate at the second position;

provide the specimen plate to the specimen image apparatus for imaging;

position the second specimen container to the second position after providing the specimen plate from the first specimen container to the specimen imaging apparatus; receive the specimen plate imaged by the specimen imaging apparatus in the second specimen container positioned at the second position from the specimen imaging apparatus;

transport the set of specimen containers from the second position to the first position by the specimen container transport mechanism so as to position the second specimen container to the first position;

take out the imaged specimen plate from the second specimen container at the first position by the specimen transport mechanism;

transport the set of specimen containers from the first position to the second position by the specimen container transport mechanism;

supply the selected rack at the first position by the rack transport mechanism; and

25

insert the imaged specimen plate into the selected rack at the first position by the specimen transport mechanism, wherein the specimen storage position and the first position are the same position.

20. The specimen storage device according to claim 19, 5 wherein in positioning the second specimen container, the controller is further configured to:

transport the set of specimen containers from the second position to the first position by the specimen transport mechanism after providing the specimen plate from the 10 first specimen container to the specimen imaging apparatus,

insert a second specimen plate into the first specimen container at the first position by the specimen transport mechanism, 15

transport the set of specimen containers from the first position to the second position by the specimen container transport mechanism so as to position the first specimen container with the inserted second specimen plate at the second position, 20

provide the second specimen plate to the imaging apparatus;

position the second specimen container at the second position by the specimen container transport mechanism after providing the second specimen plate from the first 25 specimen container to the imaging apparatus.
